1. Run the following lines and study how they work. Then state what they do and output for us.

```
df1=data.frame(Name=c('James','Paul','Richards','Marico','Samantha','Ravi','Raghu',
'Richards', 'George', 'Ema', 'Samantha', 'Catherine'),
State=c('Alaska','California','Texas','North Carolina','California','Texas',
'Alaska', 'Texas', 'North Carolina', 'Alaska', 'California', 'Texas'),
Sales=c(14,24,31,12,13,7,9,31,18,16,18,14))
aggregate(df1$Sales, by=list(df1$State), FUN=sum)
##

```

The first section of this code is setting up the data frame with the States, Names, and Sales. The next 2 sections are doing the same thing, but the first is using the in-built aggregate function to sort the data frame by state and the sum of the sales in the 2nd column. The final section does this using the dplyr library instead of the in-built tools. This library allows us to rename the column with the sum of sales as well.
